evaluation of the stomatognathic biological effects of polylactic acid cones for use in maxillary
sinus floor augmentation. A significant subset of patients with severe maxillary atrophy (MA) are
candidates for maxillary sinus augmentation and placement of implants. Traditional management of MA
has relied on surgical access, with autogenous bone from the iliac crest. The aim of the present
study was to investigate the biological behavior of a resorbable implant material that could be
placed in the sinus floor and then resorbed to allow the initial placement of implants. Cylindrical
polylactic acid (PLA) cones (1 mm x 6 mm) were tested for various biological parameters, including
attachment, proliferation, cell viability, and mineralization. Human gingival fibroblasts were
plated on PLA or hydroxyapatite disks in a 24-well plate. Viability
(3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide [MTT]) was assessed after 1, 3, 5
